## Landscape structure shaping the process of invasion

Research question How abiotic variables and resource distribution influence establishment success and spread of invasive insects?

イロト イヨト イヨト イヨ

With, Conservation Biology (2002)

Introduction	
000000	

## What do we already know?

- Urban landscape promote alien species establishment and spread (White et al. 2010)
- Urban forest, with large ratio of edge to interior habitat, are prime pathways from urban to natural area (Martin et al. 2009)
- Simplification of landscape increases the concentration of resources that are available to invasive pests (Robledo-Arnuncio et al. 2014)

### but

- Small gradient of habitat complexity (e.g. patch shape, interpatch connectivity, habitat corridors or habitat aggregation)
- Insufficient or null replications across habitat
- Global synthesis of the effect of landscape structure on pest spread?

asion

## Role of landscape composition and configuration

#### Population density

- Landscape composition  $27 \pm 0.7 \%$
- Aggregation index  $10 \pm 5 \%$

#### Occupied area

- Landscape composition  $14 \pm 4\%$
- Edge effect  $11 \pm 2\%$
- Clumpiness  $39 \pm 4 \%$

#### Rate of spread

Landscape composition  $68 \pm 4\%$ 

#### Dispersal distance

- Landscape composition  $98 \pm 4\%$
- Edge effect  $12 \pm 2\%$
- Aggregation index  $23 \pm 2 \%$

## Conclusion and future directions

## Future directions

- Relative effect of spatial pattern, dispersal abilities, and propagule pressure on dispersal success
- Source of variation in the models

## In a longer term

- Quickly assessing the spread risk of any invasive insects arriving in New Zealand (and USA!)
- Assessing and communicating about map uncertainty
- Developing specific model of spread (life strategies, directional dispersal, etc.)
- Testing management strategies
